Bendix Diaphragm Couplings offers:
- Best Balance Repeatability
- Lowest Weight
- Highest Reliability
- Ease of Installation
- Stainless Steel Diaphragms
Maximum Performance Contoured Diaphragm Couplings

**Proven Technology**
- 120,000 Diaphragm Couplings in Service.
- 10 Million hour MTBF.

Lucas’ (The former Bendix Fluid Power Division) first patent of the contoured diaphragm coupling was in 1949 and after years of research and development the first diaphragm coupling was delivered for an aircraft application in 1955. This aerospace proven technology developed by Lucas yielded the most reliable and lightweight approach to transferring torque and misalignment. In 1967 Lucas supplied the first contoured diaphragm coupling for use in the industrial petrochemical market. Lucas has supplied well over 120,000 contoured diaphragm couplings over the past four decades. Over this time our reliability has been proven with a Mean Time between Failure (MTBF) of over 10 million operating hours. Lucas is the World's Technology Leader for Power Transmission Couplings in the Industrial, Marine and Aerospace Markets. Lucas has provided diaphragm couplings in the field from as small as 4 inches in diameter too as large as 80 inches in diameter (See Figure 1).

**Lucas Superior Design**
- Light weight/simple design.
- Best balance capability.

Lucas Couplings have three major parts: a flex unit and two adapters (flange or hub) which interface with the driver and load machinery. This simple design only requires two joints and therefore has the best balance repeatability of any coupling. Competing designs require at least four joints and therefore the eccentricity between parts (5 compared to Lucas’ 3) yields significant more imbalance when a unit is reassembled.

The Lucas flex unit has contoured diaphragms located at each end of the spacer and is joined by electron beam (EB) welding. The majority of Lucas Couplings are supplied with EB Welded Flex units. Lucas has never had a radial weld failure. Thorough NDT inspection is completed on each weld to ensure a quality seam. Each Lucas flex unit is coated with multiple layers of Sermetel W, an inorganically (chemically) bonded aluminum coating, which offers a sacrificial method of corrosion protection. Any area of base material which becomes exposed to a hostile atmosphere is protected by Sermetel coating, which is more chemically reactive than steel, and will be the only surface to corrode. High temperature chemically resistant epoxy paint covers this coating.

Lucas leads the industry in sound engineering practice in designing our couplings. Some examples follow:
- Hardware is shrouded to ensure low windage.
- Helicoils are only used on special Designs.
- Torque is not transmitted through our bolt threads.
- No holes in flexure areas where bending takes place.
- Wearing and fretting avoided – no loose or rubbing parts.

**Leading the State of The Art**
- Custom 455 Stainless Steel.
- Patented Diaphragm.
- New Low Moment.
- API 610 Economic Design.

Lucas’s stainless steel diaphragm couplings (99/100 Series) have been in the field for over four years. This maximum performance design can’t be matched by any other dry coupling of comparable size. Custom 455 stainless steel material has 30% greater strength than 15-5 PH material with similar corrosion protection properties. Lucas Stainless Steel Couplings are, by far, the superior contoured diaphragm on the market.

Lucas continues to be on the leading edge of Coupling Technology. Our latest Diaphragm patent optimizes the diaphragm shape to yield the lowest stress for a given application torque and misalignment. Previous to this technology break through all diaphragm sizing was optimized only for torque using Wolff’s conventional diaphragm design. Therefore Lucas can provide the state of the art technology for a given set of conditions using either design.

Lucas’ new low moment coupling uses our standard diaphragms welded to the backside of the hub eliminating the need to put the diaphragm on top of the hub. This design will be the future benchmark for having the lowest moment since the coupling half weight will be the lowest for a comparable bore size coupling and smallest centroid distance because of the flex element position. No other coupling manufacturer has our radial weld experience and therefore cannot match this design. The customer is asked to verify that sufficient clearance between the bearing housing exist with the diaphragm. This design is ideal for those applications where lateral critical speeds are a concern.

Presently Lucas has a patent on our new API 610 & 671 Diaphragm Couplings, where we have developed a non welded joint for lower torque transmitting applications. This joint is still permanent with no additional hardware and therefore has the same balance repeatability of Lucas standard design but is more compatible for mass production.

---

88E280 Marine Diaphragm Coupling (80 inches in diameter)

That's a Diaphragm!

"The Proven Leader for Contoured Diaphragm Couplings"
Design Philosophy

• Analysis proved by test & FEA.

The contoured diaphragm that Lucas has originated and refined over the last half century has been proven time and again by field conditions as well as in house testing and analysis. Every aerospace coupling is subjected to 10 million cycles in house at greater operating stresses than the unit will be subjected to in the field. FEA and strain gage testing have been completed for many different programs including the Frame 7E Mechanical Drive Load Diaphragm Couplings. These methods have verified and validated Lucas’ proprietary computer program for stress analysis and margin evaluation used for our aerospace, marine and industrial products resulting in the industry’s highest reliability and lowest direct operating costs. This analysis integrates the loading conditions as boundary values in exactly the same fashion as Finite Element Analysis (FEA). Lucas uses multiple differential equations, which evaluate the diaphragm structure, and completes a numerical integration to develop the stresses in the diaphragm profile.

Lucas’ computer-based analysis has simplified our engineering effort such that it only takes seconds to determine the stress levels based on customer requirements. The proprietary computer program sizes and completes a data sheet with all coupling characteristics in minutes such that the customer’s quote has accurate engineering data provided. When ordering, this same data is generated into drawings, process and parts via our Computer Aided Design (CAD) and Computer Aided Manufacturing (CAM) Systems. Our new computer system releases and tracks each order from entry to shipment ensuring an on time delivery.

Coupling Ratings

Lucas Diaphragm Couplings have been rerated. Using the tables on page 3 and 5 for Maximum Continuous Torque and 125% misalignments (axial and angular) will yield a factor of safety of at least 1.25. Figure 2 shows a modified Goodman diagram for stainless steel (Custom 455). The combined mean stress (steady state torque/axial & speed) and combined alternating stress (bending & cyclic torque/axial) must have the plotted operating point fall within the area under the dotted line. Any point within this area has a minimum factor of safety of 1.25 using the proportional increase method.

Life Cycle Cost

• Lucas has lowest total system cost.

Thanks to Lucas’ experience and technology, our Diaphragm Coupling is the most reliable coupling on the market. Because of Lucas’ infinite life design no spare parts (other than hardware) are required. Therefore the total system cost of the Lucas coupling is significantly less than competing designs where downtime to replace a flex element pack will result in added inventory and labor as well as interruption of production revenue.

Materials

Hub Flanges
• Forging AISI 4340 or Equivalent
• 130,000 PSI UTS Minimum

Diaphragms
• Vacuum-Melted AMS 6414 Alloy Steel
• 170,000 PSI UTS Minimum
• Vacuum-Melted AMS 5617 Stainless Steel
• 235,000 PSI UTS Minimum

Guards
• AISI 4140
• 130,000 PSI UTS Minimum

Tubes
• AISI 4130, 4340, or Equivalent
• 130,000 PSI UTS Minimum

Shims
• Low Carbon Steel, Nickel Plated or Stainless Steel

Bolts
• AISI 4140, 4340, 6150, 8740
• Alloy Steel, Stainless Steel A286
• 150,000-200,000 PSI UTS Minimum

Nuts
• Alloy Steel, Stainless Steel A286
• 160,000 PSI UTS Minimum

Protection
• Sermetel
• High Temperature Blue Paint
## API 671 Standard & Reduced Moment Couplings

¹ Peak torque is 133% of the maximum continuous torque. Couplings subjected to transient conditions should be evaluated using the Peak torque. Limit torque is 180% of the maximum continuous torque. Couplings subjected to a “one time” momentary load should be evaluated using the Limit torque.

² Axial deflection is based on the maximum continuous torque listed. It is possible to trade off axial, torque and rated speed. Contact Lucas Engineering for additional information.

³ Parallel offset equals the value shown multiplied by the distance between flexures.

⁴ Nominal dimension is for the piloted units (88 & 100 Series). Fitted bolt units (87 & 99 Series) are 0.360 inches less than tabulated value.

⁵ The maximum bore capacity shown are for tapered shaft ends. (Consult Page 5 for straight shaft ends). The first value for each size is for our standard couplings and the second is for our low moment couplings.

4 The maximum bore capacity shown are for straight shaft ends. (Consult Page 3 for tapered shaft ends).

![Figure 5](image_url)
Selection Procedure

Step 1 - Required Data
Maximum Power ___ KW or HP
Speed Range ___ RPM
Trip Speed ___ RPM
Axial Movement ___ Inch
Driver Machine ___ Inch
Load Machine ___ Inch
Parallel Offset ___ Inch
Angular Misalign ___ Degrees
Distance Between Shaft Ends (BSE) ___ Inch
Driver Shaft End Dia. (Straight or Taper) ___ Inch
Load Shaft End Dia. (Straight or Taper) ___ Inch
Envelope Minimum Diameter ___ Inch
Special Requirements
Torquemeter, Electric Isolation, Shear Section, Backup Gear Drive

Step 2 - Torque Calculation
Calculate the normal continuous torque.

\[ T = \frac{(HP) \times (63,025)}{(KW \times 1.341)} \text{ Lb-in} \]

Speed at which HP occurs

For situations where the HP changes over the speed range, the condition generating the maximum continuous torque must be determined.

Electric motor starts, generator short circuit, compressor surge, and pump Cavitation cause single cycle peak torque requirements. This value may mandate a larger coupling selection, based upon the peak torque value of each coupling.

Step 3 - Coupling Selection
Select the coupling from page 3 or page 5, which has the maximum continuous torque greater than the calculated normal continuous torque with, specified application factor.

Step 4 - Bore Capacity
Verify the maximum bore capacity of the coupling selected is greater than the bores specified.

Step 5 - Misalignments
Verify that the coupling selected meets the angular and axial misalignments of the application.

Step 6 - Contact Lucas
Lucas will supply Coupling Selection Data Sheet in Imperial or SI units; including mass elastic, lateral and axial natural frequencies within 24 hours for standard designs!

Retrofit Applications
Lucas Diaphragm Couplings are used frequently to replace gear, disc and other dry type couplings. Contact RO-QUIP Asia Pacific with your Retrofit Requirements.

Balance Standards

Lucas has standardized on a method of balance that eliminates the errors associated with arbor balancing:

- Hubs are component balanced on a vertical machine with bores indicated concentric to the rotating table. They are balanced in two planes. Balance journals are ground on the OD of hubs concentric to the hub bore.
- The coupling is assembled with a prebalanced adapter installed within the hub bores. Concentricity of this adapter is maintained using spreader screws. Adjustment screws are used to stretch the diaphragms and rigidize the assembly.
- Alignment involves rotating the coupling on its balance journals and indicating bore diameters. By adjusting adapter screws, hub bores are aligned to within 0.0002 T.I.R. Data recorded during alignment is used to compute the eccentricity, which exists between the centerline of balance journals, and the actual centerline of the hub bore. This eccentricity is corrected for during the balance operation.

Degree of Balance
The accompanying formula is used to calculate the balance tolerance per plane for any given coupling. The value of K assigned is usually dependent upon coupling application. The lower the value of K the tighter the balance tolerance.

\[ U = \frac{KW}{N} \]

\[ U = \text{Residual Unbalance per Plane (In-Oz)} \]

\[ W = \text{Plane Weight (Lb)} \]

\[ N = \text{Max Continuous Operating Speed (RPM)} \]

\[ K = \text{Constant Denoting Degree of Balance} \]

Balance Repeatability
The coupling assembly, with its fixtures, is balanced so that the unbalance (expressed as the distance between the coupling's center of gravity and its center of rotation) is very small, generally less than 0.000050 inches.

However, even with the best of care small errors in the relative location of mating parts occur when the coupling is disassembled and then reassembled. These errors often add up to about 0.000400 inch on our couplings.

Thus, when a balanced coupling is checked for repeatability, unbalance values equivalent to U In-Oz = 0.0064 x W lbs. can be expected.

To minimize these reassemble errors the Lucas couplings:

- Are lightweight.
- Have a minimum number of assembly joints.
- Are matchmarked for consistent assembly.
- Have all machining done before balancing.
- Have no surfaces, which wear.
- Are dimensionally stable.
- Have weight-matched bolts and nuts.
- Have zero clearance diametral locating pilots (Models 88 & 100).
- Have close-fitting locating bolts (Models 68, 87 & 99).
